

Persistence Phase – Registry Modification

The command was executed using PowerShell to simulate a persistence mechanism through the Windows registry

The command adds a value to the run registry key, allowing automatic execution when the user logs in

In the SIEM, the event was identified by analyzing the process name and command line.

The behavior indicates a registry modification associated with persistence.

The screenshot shows a SIEM search interface with a query and a single result.

Query:

```
1 FROM logs*
2 | WHERE process.name == "reg.exe"
3 AND process.command_line LIKE "*cmd.exe*"
4 AND process.command_line LIKE "*CurrentVersion\\\\Run*"
5 | KEEP @timestamp, host.hostname, user.name, process.command_line, process.hash.sha256
6 | SORT @timestamp DESC
```

Result:

@timestamp	host.hostname	user.name	process.command_line	process.hash.sha256
Apr 23, 2026 @ 22:02:15.830	Asd	oolai	"C:\Windows\system32\reg.exe" add HKCU\Software\Microsoft\...	c0e25b1f9b22de445298c1e96ddfcad265ca030fa6626f61a4a4786cc4a3b7d

The activity was classified as a True positive, confirming a persistence technique

The screenshot shows a SIEM case page titled "Persistence".

Description:

During the investigation, a persistence mechanism was identified via a Run Key modification under HKCU. The reg.exe process was used to add a command to the registry. This behavior is commonly associated with attackers attempting to maintain access within the host. Since this was a clear attempt to ensure execution after reboot, it was classified as a True Positive
